

Five new books in the PRENTICE-HALL SERIES IN THE PHYSICAL AND CHEMICAL ENGINEERING SCIENCES—a series of coordinate books covering the whole range of chemical engineering operations . . .

ELECTRO CHEMICAL SYSTEMS

by John Newman of the University of California, Berkeley. A unified framework for the analysis of problems in electrochemical systems. Clearly develops the fundamentals of thermodynamics, electrode kinetics, charge and mass transport, with a view toward their application to a wide variety of electrochemical problems. Emphasizes quantitative aspects, especially the problems of scale up. Introduces the beginning student to the development, design and operation of electrochemical syntheses, processes, energy conversion and storage devices, and corrosion. Problems at chapter ends clarify and extend theories developed. Numerous examples are worked out in the text. January 1973, 448 pp., cloth (013-248922-8) \$18.95

CHEMICAL KINETICS and REACTOR DESIGN

by A. R. Cooper and V. Jeffreys, both of the University of Aston, at Birmingham. Beginning with the more fundamental aspects of the subject and a comprehensive range of problems with answers, this text serves as an undergraduate course in chemical reaction kinetics and the design and analysis of chemical reactors. Contains examples of the simple and more complicated batch reactor systems using the Laplace transform, and discusses the energy balances in batch and continuous reactors. Includes many graphical representations of the results of illustrative calculations of real systems. January 1973, 400 pp., cloth (013-128678-1) \$18.95

DYNAMIC BEHAVIOR of PROCESSES

by John C. Friedly, University of Rochester. A complete and systematic study of the analysis of unsteady state phenomena. Emphasizes physical interpretation of dynamic linear and non-linear responses and methods of analysis. Covers distributed parameter and lumped systems. Classes of system models prepare the reader to generalize readily to other systems and to diverse fields of application. Over 100 detailed examples illustrate fundamentals and varieties of applications. Over 200 figures present results graphically. Appendices include vector and matrix manipulation and Laplace transform pairs for easy reference. 1972, 590 pp., cloth (013-221242-0) \$18.95

MATHEMATICAL METHODS IN CHEMICAL ENGINEERING Volume 2:

FIRST-ORDER PARTIAL DIFFERENTIAL EQUATIONS with APPLICATIONS by Rutherford Aris and Neal R. Amundson, both of the University of Minnesota. An extended treatment of first-order equations that includes a wide variety of applications, particularly for non-mathematicians. Draws on examples from a wide range of scientific and engineering disciplines. Covers the characteristics and craft of constructing models dominated by convective phenomena; the differences between linear, quasi-linear, and nonlinear equations; the traditional methods of the Laplace transform and the connection with the calculus of variations, and more. January 1973, 416 pp., cloth (013-561092-3) \$16.50

PROCESS SYNTHESIS

by Dale F. Rudd, University of Wisconsin, Madison; Gary J. Powers, Massachusetts Institute of Technology; and Jeffrey J. Sirola, Tennessee Eastman Company. This class-tested first course in chemical engineering presents synthesis logic, and provides a motivation for introductory first-course analytical techniques of material and energy balancing. This is the first book which considers the *synthesis* of chemical processing designs in contrast to their optimization of analysis. The student will understand the history of processing, be able to screen reaction sequences for economic feasibility, make a good material balance, allocate materials to support the process of chemistry and more. January 1973, 544 pp., cloth (013-066472-3) \$15.95
