The Bumble Bees of Florida, *Bombus* spp.¹

Lionel A. Stange²

Introduction
Most bumble bees are large, social bees that produce annual colonies. Mated queens overwinter in the soil and emerge from hibernation in early spring when they feed on spring flowers and search for a suitable location, such as a former rodent burrow in the soil, to begin their colonies. These are beneficial insects that pollinate many native and ornamental plants. They can sting severely, so problem nests near human dwellings should be removed by experienced pest control operators.

Distribution
All of the social bumble bee species found in Florida range as far north as Canada (Laverty and Harder 1988). Bumble bees are less common in southern Florida. None are known from the Florida Keys. Two species, *Bombus griseocollis* and *B. pennsylvanicus*, are known from Collier County whereas a third species, *B. impatiens*, has been collected in western Palm Beach County.

Description
Bumble bees are easily recognized by the corbicula (pollen basket) on the hind tibiae in the females. Honey bees are the only other bees in Florida with this structure, but are easily recognized by their smaller size, hairy eyes, and lack of hind tibial spurs. Large carpenter bees are often misidentified as bumble bees, but these are readily distinguished from bumble bees primarily due to the absence of pubescence on the dorsum of the carpenter bee abdomen, which is somewhat glossy.

The five species of bumble bees found in Florida are usually separated by the pattern of the black and yellow pubescence.

A number of non-social *Bombus* species lost their social behavior and the ability to collect pollen, and are now cleptoparasites on colonies of pollen-collecting *Bombus* species. These cleptoparasitic species were previously listed as being in the genus Psithyrus (ITIS 2011) and are now

sometimes listed as a sub-genus. The parasitic species are easily distinguished by the lack of the corbicula. The most common of this group found in Florida is *B. variabilis*.

**Biology and Life Cycle**

Once a nest site is found, the social bumble bee queen collects pollen and lays her first brood of worker eggs. Workers emerge about 21 days after the eggs are laid and take over the duties of pollen and nectar collection as well as colony defense. The size of the workers increases with each new brood. A third caste of bumble bees, the males, is usually produced in midsummer.

**List of Social Species in Florida**

*Bombus bimaculatus* Cresson 1863, the twospotted bumble bee. Its range extends from Ontario to Maine, south to Florida, and west to Illinois, Kansas, Oklahoma, and Mississippi. Florida county records include Alachua, Clay, Franklin, Highlands, Lake, Levy, Marion, Okaloosa, and Orange.

*Bombus fraternus* (Smith) 1854, the southern plains bumble bee. Its range extends from New Jersey to Florida, and west to North and South Dakota, Nebraska, Colorado and New Mexico. Florida county records include Alachua, Franklin, Gadsden, Levy, Liberty, Orange, and St. Johns.

*Bombus griseocollis* (DeGeer) 1773, the brown-belted bumble bee. Its range extends from Quebec and Maine to Florida, and throughout the American West (DL 21011). Florida county records include Alachua, Clay, Collier, Highlands, Marion, Osceola.

*Bombus impatiens* Cresson 1863, the common eastern bumble bee. This species is native from Ontario to Maine and south to Florida and was introduced in California and in British Columbia, Canada (EOL 2011). Florida county records include Alachua: Bradford, Calhoun, Escambia, Franklin, Jackson, Gadsden, Highlands, Levy, Liberty, Okaloosa, Orange, Palm Beach, Polk, Santa Rosa.

*Bombus pennsylvanicus* (DeGeer) 1773, the American bumble bee. Its range extends from Quebec and Ontario, Maryland south to Florida, then west to Minnesota, South Dakota, Nebraska, Colorado, New Mexico, and Mexico (Anonymous 2011). Florida county records include Alachua, Bradford, Collier, Escambia, Flagler, Highlands, Lake, Lee, Levy, Marion, Orange, Putnam, Sarasota, Santa Rosa.

*Bombus terricola* Kirby 1837, the yellow-banded bumble bee. Originally, this species extended from Nova Scotia to Florida, west to British Columbia, Montana and South Dakota. While once common, it has declined dramatically.

**Key to the Bumble Bees in Florida**

1. Antenna with 12 segments; abdomen with six visible terga; tip of abdomen pointed, with stinger; corbiculae on hind tibiae (not *Psithyrus*); active all summer; females (queens and workers) . . . . . 2

1'. Antenna with 13 segments; abdomen with seven visible terga; tip of abdomen round, no stinger; hind tibia lack corbiculae; active from middle of summer till winter; males . . . . . 7

2. Hind tibia relatively slender, without corbicula; cleptoparasitic forms . . . . B. variabilis

2'. Hind tibia with well-developed corbiculae (pollen-collecting Bombus spp.) . . . . 3

3. Posterior half of scutum and all of scutellum with black pubescence (Fig. 2) . . . . B. pennsylvanicus

3'. Posterior half of scutum and scutellum with some yellow pubescence . . . . 4

4. Dorsum of thorax with a conspicuous, transverse band of black pubescence between wing bases (Fig. 1) . . . . B. fraternus

4'. Dorsum of thorax without transverse black band between wing bases . . . . 5

5. Tergum II of abdomen entirely black (Fig. 3) . . . . B. impatiens

5'. Tergum II of abdomen with yellow pubescence medially at base (Figs. 4, 5) . . . . 6

6. Lateral ocellus distinctly below supraorbital line (Fig. 6) . . . . . B. griseocollis

6'. Lateral ocellus at level of supraorbital line (Fig. 7) . . . . B. bimaculatus

7. Hind tibia convex, densely pubescent on outer surface; gonostylus much exceeding apex of gonocoxites; cleptoparasitic forms . . . . . 8

7'. Hind tibia somewhat flattened, sparsely pubescent on outer surface; gonostylus not much exceeding apex of gonocoxite (pollen-collecting Bombus spp.) . . . . 8

8. Eyes usually converging above, lateral ocelli nearer margins of eyes than to each other; malar space no more than 1/4 basal width of mandible . . . . . 9

8'. Eyes about parallel, lateral ocelli closer to each other than to eye margins; malar space about as long as basal width of mandible . . . . . 10

9. Malar space nearly obliterated; eye nearly touching base of mandible . . . . . 11

9'. Malar space distinct; eye somewhat removed from base of mandible . . . . B. fraternus

10. Dorsum of thorax with a median band of black pubescence . . . . B. pennsylvanicus

10'. Dorsum of thorax entirely yellow pubescent or with median patch of black hairs that don't reach tegulae . . . . . 11

11. Segment two of abdomen entirely black pubescent . . . . B. impatiens

11'. Segment two of abdomen with at least some yellow pubescence . . . . B. bimaculatus
