TAXONOMIC NOTES ON *HEMICYCLIOPHORA* DE MAN
(NEMATODA: *HEMICYCLIOPHORIDAE*)

by

M. W. BRZESKI and T. S. IVANOVA

The genus *Hemicycliophora* de Man was revised by Brzeski (1974) who included 60 valid species. Since the publication of his paper 10 new species have been described, with another described here.

Another important contribution to the taxonomy of the genus is that of Eroshenko (1976) in which he lists 77 species, but does not recognize the synonyms proposed by Brzeski (1974).

The measurements and symbols used in this paper are the same as those proposed by Brzeski (1974).

Hemicycliophora italiae sp. n. (Fig. 1)

For measurements see Table I.

Outer cuticular layer loosely surrounds body. Annules rounded on both cuticular layers. Lateral field marked by anastomoses or breaks, no longitudinal lines or markings seen. Lip region with two annules. Lateral lips lower than the submedian ones. Labial disc slightly protruded, rectangular to rounded. Stylet knobs posteriorly elongated, with large cavity. Spermatheca filled with sperm. Vulval lips modified, body narrowed immediately posterior to vulva. Tail narrow slightly more dorsally than ventrally, tail end more or less offset. Annulation disappears on both cuticular layers of tail end. Tail tip rounded.

Male unknown.

Holotype female and 29 paratype females deposited in the nema-

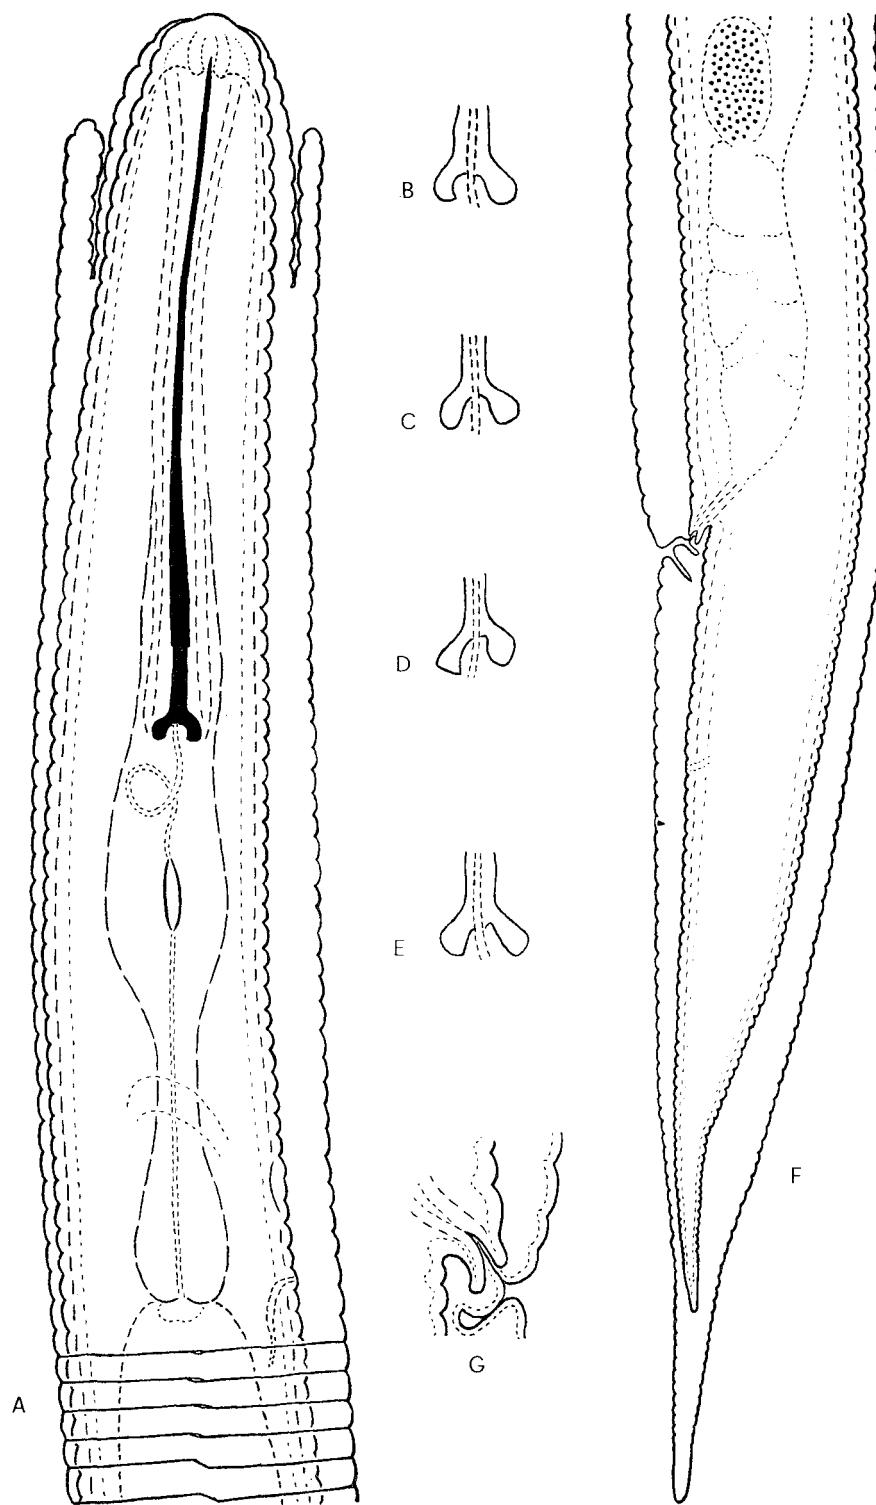

Fig. 1 - *Hemicyclophora italiae* sp. n.: A, anterior body part of female; B-E, variation of stylet knobs; F, posterior body part of female; G, vulval lips.

tode collection of the Research Institute for Vegetable Crops, Skieriewice, Poland.

Type locality and habitat: this species has been found in the following localities in Italy: Pescara, Davalos near Pescara, and Zapponeta in the province of Foggia. The holotype was selected from the Pescara population. In both localities near Pescara *H. italiae* sp. n. was found in nursery soil in the root zone of *Pinus* sp. In Zapponeta it was found in soil near onion roots. All the localities are very close to the Adriatic coast.

Differential diagnosis: *H. italiae* sp. n. is close to *H. conida* Thorne, from which it differs by being larger, having a longer stylet, more annules, and smooth cuticle without any ornamentation or lines on the lateral field. The tail end of *H. italiae* sp. n. is generally more offset than the tail of *H. conida*.

Hemicycliophora subaolica Jairajpuri et Baqri, 1973
(Fig. 2 and 3)

For measurements see Table II.

Outer cuticle adpressed to the body, except for the tail region where it is looser. Outer cuticular annules flattened, inner annules rounded. Lateral field undifferentiated, sometimes marked by anastomoses. Outside lateral field numerous delicate scratches seen on most of the females. Lip region with three, rarely two annules. Labial disc rounded. Lateral lips lower than the submedian ones. Stylet knobs rounded, without cavity. Spermatheca filled with sperm. Vulval lips modified. Tail conical, narrows equally on dorsal and ventral sides. Tail end annulation distinct.

Male with four incisures on lateral field. Head flattened on anterior end, sometimes slightly expanded, delicately annulated. Excretory pore 141-147 μm from the anterior end. The closest distance between the ends of spicule 21-27 μm , gubernaculum 6-7 μm .

The above description is proffered to extend the range of the variability of the species. It is based on the specimens collected in Tadzhikistan in the various places of Gissarskij and Karateginskij mountain ranges, in soil surrounding the roots of *Amygdalus bucharica* Korsh., *Prunus sogdiana* Vass., *Sorbus persica* Hedl. et Colutea, *Juniperus seravschanica* Komm., *Cerasus* sp., *Malus* sp. and *Rosa* sp. Roots of infested cherry and almond trees were shortened and thick-

ened (Fig. 4), and many nematodes feeding on the diseased roots were observed.

The above description differs from the description of the type specimens (Jairajpuri et Baqri, 1973) in the following points:

- lateral field undifferentiated in types, while some females studied by us show discontinuity of annulation on lateral field,
- longitudinal lines absent in types, but very delicate scratches seen on most of females from Tadzhikistan,
- head bearing two annules in the original description and two and a half on the drawing 4B of Jairajpuri and Baqri (1973), while 2 - 3 annules were observed in our material.

Since no other differences can be seen, we conclude that the Tadzhikistan specimens are conspecific with *H. subaolica*. This species has been described from mountains in Himachal Pradesh, the north Indian state.

Hemicycliophora sheri Brzeski, 1974

For measurements see Table III.

H. sheri has been described on the basis of 6 females from Cali-

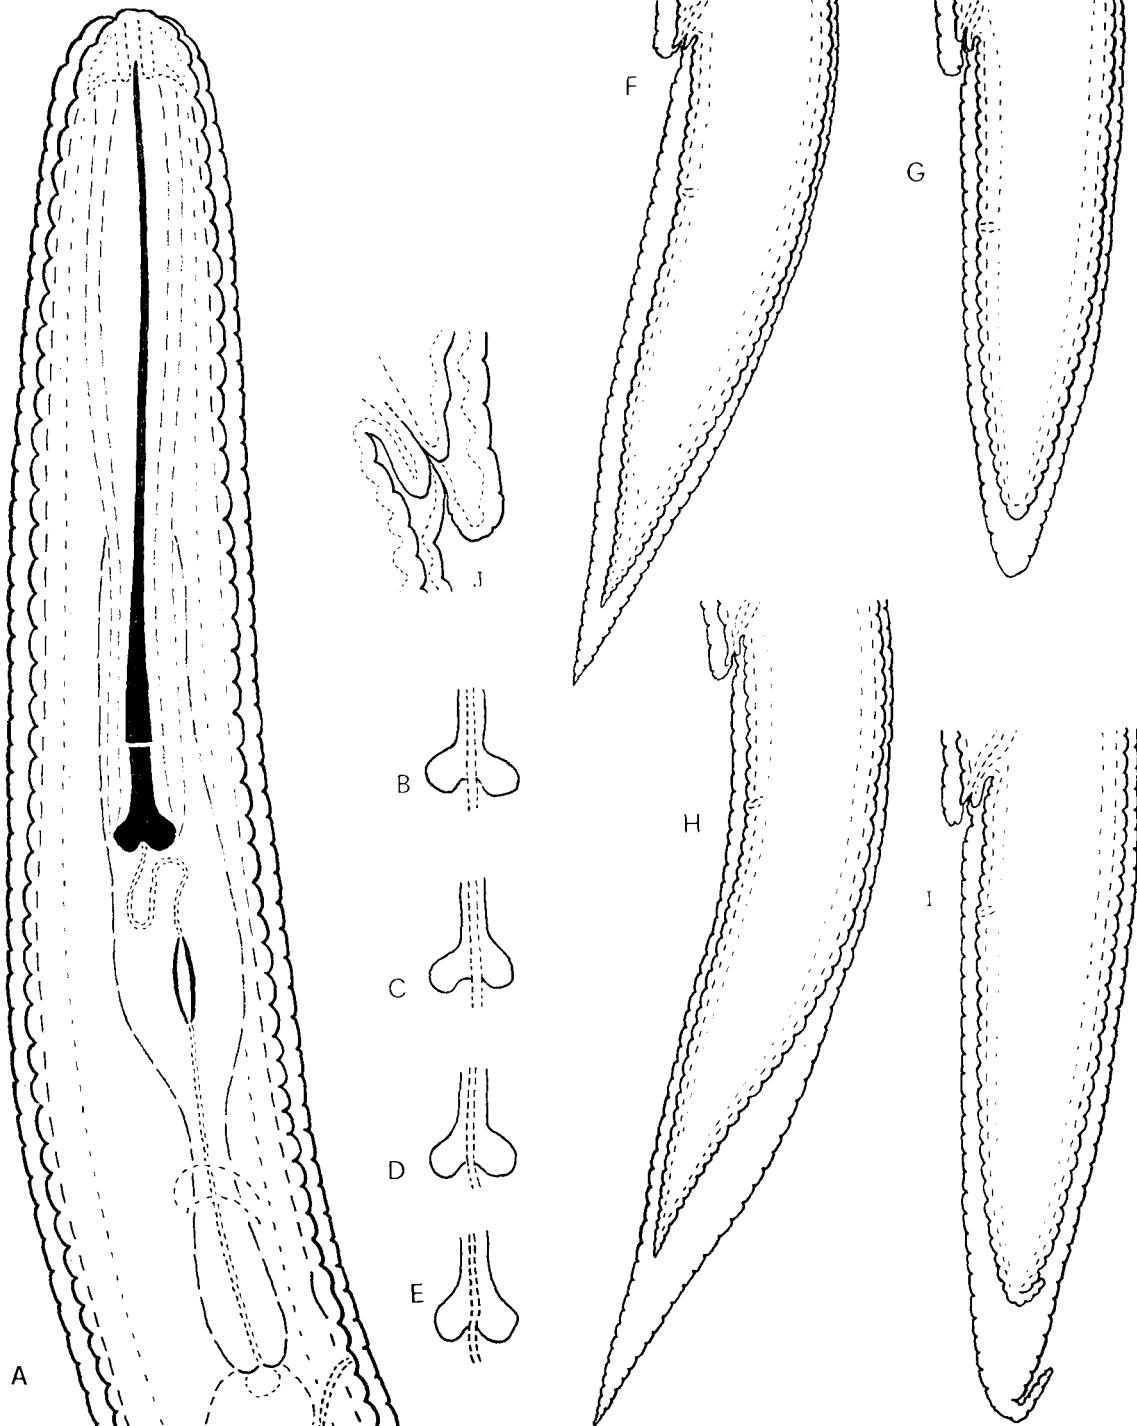

Fig. 2 - *Hemicyclophora subaolica* - female: A, anterior body part; B-E, variation of stylet knobs; F-I, variation of posterior body part; J, vulval lips.

fornia. Ten additional females were collected in a grass soil from Kansas, U.S.A. These females differ from those of the type population by being larger, although the number of annules is similar. This species is characterized by large rounded labial disc, three lip annules, stylet knobs with cavity, moderately elongated vulval lips, and slightly offset tail end.

Note on giant females

Giant females were reported by Jairajpuri and Baqri (1973) in their description of *H. sobaolica*, and a similar variation was found in a population of *H. italiae* (Table I). These females are larger and have more annules, but otherwise they do not differ from other specimens. Although not shown experimentally, we concur with the opinion of Jairajpuri and Baqri (1973) that they are morphological variants. The presence of giant females in some populations emphasises the statement made earlier (Brzeski, 1974) that it is always risky to base an identification on a single female.

Key for identification of *Hemicycliophora* females

This key is based on one published by Brzeski (1974). Some species are inserted twice, because certain characters (mainly the

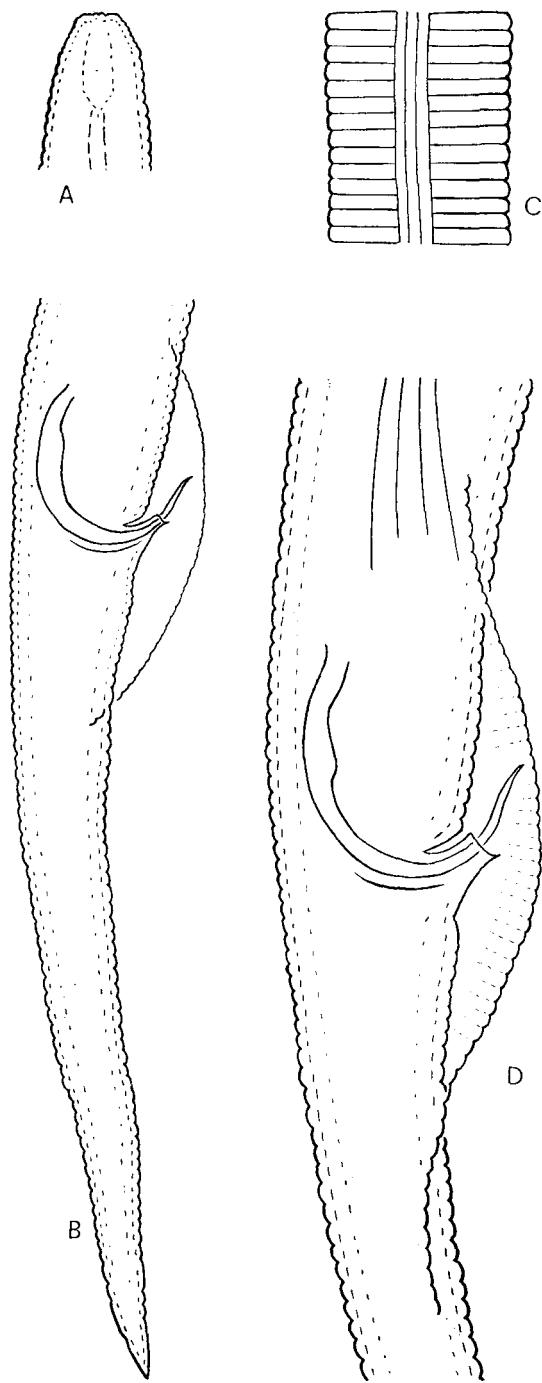

Fig. 3 - *Hemicycliophora subaolica* - male: A, head; B, tail; C, part of lateral field; D, cloacal region.

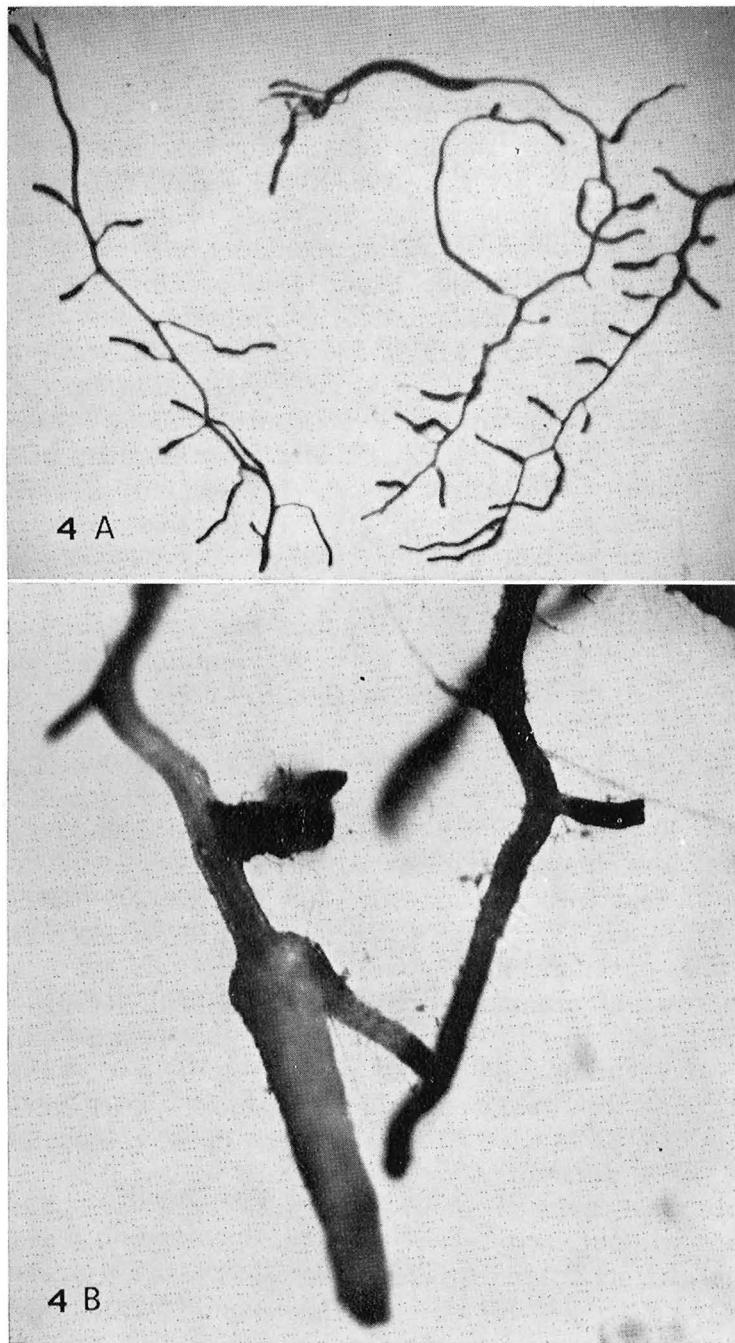

Fig. 4 - Roots infested by *Hemicycliophora subaolica*: A, *Amygdalus bucharica*; B, *Cerasus* sp.

cuticular sculpture) show variation among populations of the same species. We feel that it should facilitate identification.

S U M M A R Y

Hemicyclophora italiae sp. n. from Italian Adriatic coast is described. It differs from *H. conida* Thorne, 1955 by being larger, having longer stylet, more annules, and cuticle without any ornamentation. *H. subaoatica* Jairajpuri et Baqri, 1973 is redescribed from specimens collected in the mountains of Tadzhikistan, U.S.S.R., and *H. sheri* Brzeski, 1974 is reported from Kansas, U.S.A. A key for the identification of *Hemicyclophora* females is given. The genus contains a total of 71 species.

RIASSUNTO

Note tassonomiche su *Hemicycliophora* de Man (Nematoda: Hemicyclophoridae).

È descritta *Hemicyclophora italiae* n. sp., raccolta in varie località della costa adriatica italiana. Essa differisce da *H. conida* Thorne, 1955 per le maggiori dimensioni del corpo e dello stiletto e per avere un maggior numero di anelli e la cuticola senza ornamentazioni. Viene ridescritta *H. subaolica* Jairajpuri et Baqri, 1973 su esemplari raccolti sulle montagne del Tadzhikistan, URSS, e *H. sheri* Brzeski, 1974 è segnalata per la prima volta in Kansas, U.S.A. Viene, inoltre, proposta una chiave per l'identificazione delle 71 specie appartenenti a questo genere.
