# NEMATODES FROM ITALIAN SAND DUNES. 6. TWO NEW AND THREE RARE SPECIES OF CEPHALOBIDAE (NEMATODA) 

L. Orselli and M.T. Vinciguerra<br>Dipartimento di Biologia Animale, Università di Catania, 95124 Catania, Italy

#### Abstract

Summary. During a nematode survey of the coastal sand dunes of Sicily (Italy) two new and three rare species of Cephalobidae were found, which are described and illustrated. Chiloplacus insularis sp. n. is characterized by labial probolae distally concave, lateral fields with five incisures, long post-vulval sac and rounded tail terminus. Cervidellus psammophilus sp. n. is mainly characterized by the shape of labial probolae, which bifurcate twice, and by the strongly crenate lateral fields. Nothacrobeles sheri Allen et Noffsinger, 1971 and Paracrobeles psammophilus Navarro et Lluch, 1999, found for the first time after their specific recognition, are redescribed. Males of Stegelleta ophioglossa Andrássy, 1967 are described for the first time.

During a nematode survey of the coastal sand dunes of Sicily (Italy) two new and three known but rare species of Cephalobidae were found, which are described and illustrated.

## MATERIALS AND METHODS

Samples were collected with a plexiglass soil corer to a depth of 60 cm . Nematodes were extracted by centrifugation, killed and fixed in hot $4 \%$ formalin and processed to anhydrous glycerin. Measurements were made with the aid of a camera lucida. For SEM, some glycerin embedded specimens of each species were first washed with gradually added distilled water; subsequently they were dehydrated by a gradual series of ethanol concentrations increasing to $100 \%$; then critical point dried with $\mathrm{CO}_{2}$, mounted on stubs and coated with gold.

## DESCRIPTIONS <br> CHILOPLACUS INSULARSS sp. n.

(Figs 1 and 2; Table I)
Female. Body more or less curved, often S-shaped in heat fixed specimens. Cuticle annulated; each ring 3.5$4.0 \mu \mathrm{~m}$ long at level of pharynx. The annules are furrowed by light longitudinal incisions. Lateral fields with five incisions which become three after the phasmids. Lip region characterized by three prominent labial probolae, symmetrical, appearing deeply incised distally by the light microscope, but with the external surface concave as viewed by SEM. The three cephalic probolae, flat and low, bear six labial and four cephalic papillae. Amphids small and round at the base of cephalic papillae. Pharynx cylindroid with short isthmus enlarging into a spherical basal bulb. Corpus 5-6.5 times as
long as isthmus. Nerve ring at $81-86 \%$ of pharynx length. Excretory pore often obscure, just before nerve ring. Cardia short, hemispheroid, $5.5-7.5 \mu \mathrm{~m}$ long. Reproductive apparatus prodelphic. Vulva a transverse

slit, with lips not always protruding. Vagina oblique, directed anteriad, without sclerotizations, 17.5-19 $\mu \mathrm{m}$ long. Ovary reflected twice; oviduct with a spermathaeca $42-45 \mu \mathrm{~m}$ long; post-vulval sac rather long, $4-5$ times the corresponding body width. Tail conoid-cylindroid with 13-16 annuli on ventral surface and bluntly rounded terminus. Phasmids at $46-53 \%$ of tail length.

Male. Similar to female except for sexual characters. Spicules 1.2-1.5 times as long as anal body width. Gubernaculum just longer than half spicules length. Five pairs of post-anal papillae located as shown in Fig. 1D and a single pre-anal papilla. Tail conoid with rounded terminus.

## Diagnosis and relationship

Cbiloplacus insularis sp. n . is characterized by large size, labial probolae distally concave, lateral fields with five incisures, long post-vulval sac and rounded tail terminus. From the other species with five incisures in the lateral fields it can be distinguished for the following characters: from C. sclerovaginatus Sumenkova et Razzhivin, 1968, C. saccatus Loof, 1971, C. tenuis Rashid et Heyns, 1990 and C. longiuterus Rashid et Heyns, 1990 it differs in much larger size. Moreover it differs from $C$. sclerovaginatus by lacking the vaginal sclerotization and from C. tenuis since only three lateral incisures reach tail end. It differs from C. magnus Rashid et Heyns, 1990 by having longer postvulval sac ( $132-167 \mu \mathrm{~m}$ vs $68-135 \mu \mathrm{~m})$ and only three lateral incisures reaching tail end. From C. kralli Bagaturija, 1973 it differs by having post-vulval sac and lower and less incise labial probolae. From C. quinquesulcus Ivanova, 1968, C. quadricarinatus (Thorne, 1925) Thorne, 1937 and C. subtenuis Rashid et Heyns, 1990 it differs in the different shape of labial probolae, length of post-vulval sac and absence of pre-anal ventro-lateral pairs of papillae in male. Moreover it differs from C. subtenuis because in the latter the number of lateral incisures does not change after the
phasmids. The specimens from Sardinia described by Zullini (1978) as C. quadricarinatus agree rather well with the description of C. insularis and might belong to this species.

## Type locality and babitat

Siculiana (Agrigento, Italy): sand dunes. Other localities: Selinunte (Trapani), Eraclea (Agrigento), Manfria (Caltanissetta), mouth of river Irminio (Ragusa).

## Type specimens

Holotype and one male paratype deposited in the collection of the Dipartimento di Biologia Animale, University of Catania; one female and one male paratype in the Allatrendszertani Intézet, University of Budapest, Hungary; one female and one male paratype in the Instituut voor Dierkunde, University of Gent, Belgium.

## Derivatio nominis

The specific epithet is the Latin word insularis $=$ island inhabiting.

## CERVIDELLUS PSAMMOPHILUS sp. n.

(Figs 2 and 3; Table II)
Female. Body ventrally curved or C-shaped. Cuticle strongly annulated, appearing very refractive in the optical section; each ring $2-3 \mu \mathrm{~m}$ long at level of pharynx. Lateral fields delimited by three longitudinal incisions, of which the median is hardly visible at the light microscope while the lateral ones are strongly refractive and crenate. Labial probolae deeply incised, Y-shaped, branching at $60-70 \%$ of their length; each branch bifurcates again before the apex. Six cephalic probolae, each constituted by five petaloid lobes whose length decreases symmetrically from the largest central one. The

Fig. 2. - (A-C) C. insularis sp. n.: A and B, lip regions; C, male tail; (D-E) Cervidellus psammophilus sp. n.: D, lip region; E, male tail; (F-H) Nothacrobeles sheri: F, lateral field; G and H, lip region. (scale bar $=\mathrm{A}, 4 \mu \mathrm{~m} ; \mathrm{B}$ and G, $5 \mu \mathrm{~m} ; \mathrm{C}$ and $\mathrm{E}, 12 \mu \mathrm{~m} ; \mathrm{D}, 4.5$ $\mu \mathrm{m} ; \mathrm{F}, 7 \mu \mathrm{~m} ; \mathrm{H}, 6 \mu \mathrm{~m})$.

Fig. 3. - C. psammopbilus sp. n.: A, anterior region; B, anterior end; C, female genital apparatus; D, schematized lip structure; E, male tail; F, female tail; G, lateral fields.
cephalic probolae bear the six labial and the four cephalic papillae and the small, round amphids. Pharynx cylindroid, ending with a basal bulb. Corpus 2.3 3.5 times as long as isthmus. Nerve ring at $60-73 \%$ of pharynx length. Excretory pore at the same level, 101$125 \mu \mathrm{~m}$ from anterior end. Cardia short, hemispheroid; terminal part of rectum appearing very refractive. Reproductive apparatus prodelphic. Vulva a transverse slit, with lips not protruding. Vagina without sclerotizations, $5-7.3 \mathrm{~mm}$ long. Ovary reflexed; oviduct with a spermathaeca $23-30 \mu \mathrm{~m}$ long containing sperms; postvulval sac 1.6-2.7 corresponding body width long. Tail elongate conoid, straight, with pointed, smooth terminus. Phasmids at 20-30\% of tail length.

Male. Similar to female except for sexual characters. Spicules ventrally curved, 0.9-1.2 times as long as anal body width. Gubernaculum as long as half spicules length. Five pairs of post-anal papillae located as shown in Fig. 3E. Tail conoid with acute, not annulated, terminus, 1.6-2.5 times as long as anal body width. Phasmids at $35-45 \%$ of tail length.

## Diagnosis and relationship

Cervidellus psammophilus sp. n. is mainly characterized by the shape of labial probolae, which bifurcate twice, and by the strongly crenate lateral fields. It resembles C. hamatus Thorne, 1937 and C. alutus (Siddiqi, 1993) Shahina et De Ley, 1997, which have simi-
lar labial probolae, but differs from the former in the lateral fields structure (with three incisures vs. five) and in the relatively longer ( $c=5.7-8.8$ us 14 ) female tail and from the latter by lacking a "double" cuticle and in the sharply pointed male tail end (in C. alutus it is rounded).

## Type locality and habitat

Selinunte (Trapani, Italy): sand dunes. Other localities: Eraclea (Agrigento), Vendicari (Siracusa), Manfria (Caltanissetta), mouth of river Irminio (Ragusa).

## Type specimens

Holotype and 10 female and 22 male paratypes deposited in the collection of the Dipartimento di Biologia Animale, University of Catania; one female and one male paratype in the Allatrendszertani Intézet, University of Budapest, Hungary; one female and one male paratype in the Instituut voor Dierkunde, University of Gent, Belgium; one female and one male paratype in the Museum of Natural History, Stockholm, Sweden; one female and one male paratype in the Nematology Laboratory, USDA, Belltsville, USA.

## Derivatio nominis

The specific epithet is of Greek origin and means "which likes sand".

## NOTHACROBELES SHERI Allen et Noffsinger, 1971

(Figs 2 and 4; Table III)
Female. Body cylindroid, tapering towards the posterior end. Cuticle transversely annulated; each annule, $4.5-7 \mu \mathrm{~m}$ long, shows punctuation in three rows, more or less evident in the various specimens and, due to the presence of several longitudinal furrows, appears to consist of a sequence of rectangular lobules. Lateral fields crenate, with four longitudinal incisions at midbody; they start anteriorly as a single field delimited by two incisions; then, at level of pharynx base, a median line appears, which posteriorly bifurcates forming the two internal lines. The three labial probolae bifurcate at their base appearing as six long triangular projections; their margins fringed and their apices ending with a median lobule. The base of each probola projects outwards with a laminar process; the tangential ridges between the probolae appear fringed. Cephalic probolae with serrate distal margins; in each of the three cephalic primary axils two long and slender guard processes are present. Pharynx cylindroid, ending with a basal bulb. Corpus 3.3-4.6 times as long as isthmus. Nerve ring at the level of isthmus anterior end, at 65-76\% of pharynx length; excretory pore in proximity of nerve ring, 140$190 \mu \mathrm{~m}$ from anterior end. Vulva transverse; vagina without sclerotizations, 9-12.5 $\mu \mathrm{m}$ long. Ovary prodelphic, reflexed; oviduct with a spermathaeca $37.5-55 \mu \mathrm{~m}$ long; a post-vulval sac, 1-2 body widths long, is present.

Table II. Measurements of Cervidellus psammophilus sp.n. (all measurements are in $\mu \mathrm{m}$ except L in mm ).

Fig. 4. - Nothacrobeles sheri: A, anterior region; B, anterior end; C, female genital apparatus; D, male tail; E, female tail.

Rectum 0.7-1.2 times anal body width long, provided with two rectal glands. Tail conoid, with pointed, nonannulated terminus. Phasmids at $15-25 \%$ of tail length.

Male. Similar to female except for sexual characters. Spicules 1-1.2 times as long as cloacal body width. Gubernaculum just longer than half spicule length. Three pairs of pre-anal papillae-like organs are present. Five pairs of post-anal papillae. Tail conoid with acute terminus. Phasmids at $25-35 \%$ of tail length.

## Localities and habitat

Israel: soil; Italy (southeastern coast of Sicily): dune sand.

## Remarks

This species was originally described from Israel (Allen and Noffsinger, 1971) and never reported again. The characteristics of the population from Sicily fit well with the original description.

## STEGELLETA OPHIOGLOSSA Andrássy, 1967 <br> (Figs 5 and 6; Table IV)

Female. Body ventrally bent or S-shaped. Cuticle annulated, each annule 2-2.5 $\mu \mathrm{m}$ long at mid-body, and crossed by 14 longitudinal prominent ridges. Lateral fields two, with crenate margins, very close to each oth-

Fig. 5. - Stegelleta ophioglossa: A, anterior region; B, anterior end; C, female genital apparatus; D, female tail; E, male tail.
er. Labial probolae long, Y-shaped, each with a wide, tongue-like basal part bifurcating at about $40 \%$ of its length; branches slender, rope-like. Lips globular, without cephalic probolae, bearing the anterior sensilla. Stoma weakly sclerotized. Pharynx cylindroid, ending with a basal bulb. Nerve ring at $72-78 \%$ of pharynx length, where the isthmus starts. Excretory pore opening nearby, at 122-147 $\mu \mathrm{m}$ from anterior end. Vagina slightly protruding, without sclerotizations, $7-8 \mu \mathrm{~m}$ long; spermatheca well developed, 24-26.5 $\mu \mathrm{m}$ long; post vulval sac short, 0.7-1.3 body diameter long. Tail cylindroid, straight, with blunt terminus, 2.3-2.9 anal body width long. Phasmids at $15-30 \%$ of its length.

Male. Similar to female in most respects. Spicules cephaloboid, 1.2-1.7 cloacal body width long. Gubernaculum very slender, epsilon-shaped, slightly longer than half spicule. Tail conoid, slightly ventrally curved, with rounded terminus. Phasmids at $25-35 \%$ of tail length.

## Localities and babitat

Mongolia, Hungary, Venezuela, Uzbekistan, Senegal, Italy (southeastern coast of Sicily): dune sand, steppe, wet sand, marginal soil.

## Remarks

Stegelleta opbioglossa is a rather uncommon, even though widespread, species of which males have never

Table III. -- Measurements of Nothacrobeles sheri (all measurements are in $\mu \mathrm{m}$ except L in mm ).

Fig. 6. - (A-C) S. ophioglossa: A, lip region; B, male tail; C, detail of cuticle; (D-G) Paracrobeles psammophilus: D, lateral field; E, female tail; F and G, lip regions. (scale bar $=\mathrm{A}, 4.5 \mu \mathrm{~m} ; \mathrm{B}, 12 \mu \mathrm{~m} ; \mathrm{C}$ and $\mathrm{F}, 6 \mu \mathrm{~m} ; \mathrm{D}, 9 \mu \mathrm{~m} ; \mathrm{E}, 10 \mu \mathrm{~m} ; \mathrm{G}, 5 \mu \mathrm{~m}$ ).
been found so far. The characteristics of our specimens agree well with those of the original description, except for the rather larger size.

## PARACROBELES PSAMMOPHILUS Navarro et Lluch, 1999

(Figs 6 and 7; Table V)
Female. Body straight or slightly curved ventrad, tapering towards both extremities. Cuticle annulated; each annule $4.0-5.0 \mu \mathrm{~m}$ long at mid-body, sub-divided into numerous rectangular lobules by fine and shallow longitudinal furrows and covered with small protuberances which at light microscope appear as a scattered punctuation. Lateral fields two, originating at level of metacorpus. Lip region very elaborate. Each of the three labial probolae consists of a short laminar base (about $15 \%$ of its total length) which bifurcates giving rise to two long pointed tentacles. The six lips give rise to as many cephalic probolae, each of which projects anteriad with three tapering prongs, the median of which is clearly shorter

than the lateral ones. In each primary axil there is a guard process much shorter than the cephalic probolae; in the secondary axils there are two short processes. The contiguous prongs of a cephalic probola or of adjacent probolae are sometimes linked by fine anastomoses (visible only by SEM) which give the whole cephalic structure a complicated and somewhat irregular pattern. Pharynx cylindroid; metacorpus very wide, its lumen expanded and lined by sclerotized walls; corpus ending with a valvular apparatus, 2.8-3.7 times as long as isthmus. Nerve ring at level of isthmus, at 70.7-82.4\% of pharynx length. Excretory pore not always visible, located at $114-139 \mu \mathrm{~m}$ from the anterior end, just anterior to

Fig. 7. - Paracrobeles psammophilus: A, anterior region; B, anterior end; C, female genital apparatus; D, female tail; E, male tail; F, schematized lip structure.
nerve ring. Cardia small, emispheroid. Reproductive apparatus prodelphic with reflected ovary, spermatheca 30 $37 \mu \mathrm{~m}$ long and a large post-vulval sac with a large nucleus in the wall. Vulva lips not prominent; vagina without sclerotizations, 14-18.5 $\mu \mathrm{m}$ long. Tail conoid, straight, with pointed terminus, $2.2-2.8$ anal body width long. Phasmids at $20-26 \%$ of tail length.

Male. Similar to female in most respects. The spicules, 2-3 cloacal body width long, are very slender and recurved ventrad. Gubernaculum thin, its length about two-fifth that of the spicules. Tail conoid, pointed, only slightly bent ventrad. Papillae: one pair precloacal and five pairs in the tail, located as in figure 5 E , often obscure. Phasmids at $33-46 \%$ of tail length.

## Localities and habitat

Dehesa de El Saler (Spain): sandy soil of a clearing in a Pinus halepensis Mill. forest; mouth of the river Irminio (Ragusa, Italy): dune sand.

## Remarks

Paracrobeles psammophilus belongs to a genus of Cephalobidae which differs from all the others in the peculiar structure of the metacorpus; moreover the spicules in both species described are relatively longer and more slender than usually. In this species the spicule length is much longer than in P. laterellus Heyns, 1968 and its shape is unique among Cephalobidae. The characteristics of the population from Sicily agree well with the original description of the species, even though here the spicules are longer than in the population from Spain ( $68-81 \mu \mathrm{~m}$ vs. $42-57 \mu \mathrm{~m}$ ).
