

THE SYSTEMATIC DISTRIBUTION OF VASCULAR EPIPHYTES: AN UPDATE

W. JOHN KRESS

Marie Selby Botanical Gardens, 811 South Palm Avenue,
Sarasota, Florida 33577

ABSTRACT. The list of vascular plant families and genera containing epiphytic species published by Madison (1977) is updated here. Ten percent (23,456 species) of all vascular plant species are epiphytes. Seven percent (876) of the genera, 19 percent (84) of the families, 45 percent (44) of the orders and 75 percent (6) of the classes contain epiphytes. Twenty-three families contain over 50 epiphytic species each. The Orchidaceae is the largest family of epiphytes, containing 440 epiphytic genera and 13,951 epiphytic species. Forty-three genera of vascular plants each contain over 100 epiphytic species.

In 1977 Madison published a list of the vascular plant families and genera that contain epiphytic species. Madison compiled this list from literature reports, consultation with taxonomic specialists, and a survey of herbarium material. He reported that 65 families contain 850 genera and 28,200 species of epiphytes. His total accounted for about ten percent of all species of vascular plants.

Madison's list was the most comprehensive compilation of vascular epiphytes since the works of Schimper (1888) and Richards (1952) upon which it was partly based. Since the publication of Madison's list many additional records of epiphytic species have been compiled. These additions are partly due to literature citations unavailable to Madison as well as more recently acquired knowledge of many tropical plant families. Two recent symposia on the biology of tropical epiphytes, one at the Marie Selby Botanical Gardens (see papers in this volume) and the other at the Missouri Botanical Garden (Ann. Missouri Bot. Gard., in press), underscored the need to update Madison's list by the addition of these new reports and the correction of omissions (e.g., *Lycopodium*) and erroneous inclusions (e.g., *Ananas*, *Carludovica*).

Madison listed the epiphytic genera in all families of vascular plants except for the Orchidaceae, which is the largest family of plants and has the most epiphytic members. Instead he provided an estimate that the orchids accounted for approximately 500 genera and 20,000 species of epiphytes. For the sake of completeness a compilation is included here of epiphytic orchid genera that is based on an exhaustive survey of the family by Atwood (1986).

The definition of an epiphyte used here follows those of Schimper (1888), Richards (1952) and Wallace (1987). The term epiphytes includes "true epiphytes," "hemi-epiphytes," "casual epiphytes," and in some cases "semi-epiphytic climbers." True epiphytes, or holo-epiphytes, are

those plants that normally spend their entire life cycle perched on another plant and receive all mineral nutrients from non-terrestrial sources. Hemi-epiphytes normally spend only part of their life cycle perched on another plant and thus some mineral nutrients are received from terrestrial sources. Hemi-epiphytes either begin their life cycle as epiphytes and eventually send roots and shoots to the ground (primary hemi-epiphytes), or begin as terrestrially established seedlings that secondarily become epiphytic by severing all connections with the ground (secondary hemi-epiphytes). Species in which some individuals of a population function as true epiphytes while others are terrestrial are called casual epiphytes. Semi-epiphytic climbers are vines that climb by adventitious roots which partly function in water and mineral uptake (Wallace, 1987). Accidental epiphytes and parasites are excluded from this survey. The above categories, with the exclusion of semi-epiphytic climbers, correspond to the definition of epiphytes recognized by Madison.

MATERIALS AND METHODS

Madison's list of epiphytic genera (1977: Table 1) served as the starting point for this survey. His list was compiled from literature reports, his own collections, the advice of taxonomic specialists and a survey of specimens at the Harvard University Herbaria (A and GH). The list has been updated from several sources. First, additional literature citations of epiphytes appearing since the publication by Madison were reviewed. However, not all literature reports of epiphytes included here have been verified by specialists. Casual anecdotal accounts generally were omitted. Second, the large collection of epiphytic plants in the research collection at the Marie Selby Botanical Gardens was a source of information. Third, new estimates for plant families containing epiphytes were provided by taxonomic specialists studying those families (i.e., Araceae,

Asteraceae, Bromeliaceae, Cactaceae, Clusiaceae, Cyclanthaceae, Ericaceae, Marcgraviaceae, Melastomataceae, Onagraceae, Orchidaceae, Rubiaceae, Scrophulariaceae, and Solanaceae).

In order to obtain an estimate of the distribution of the epiphytic habit in vascular plants, the list of genera is presented in an hierarchical classification that reflects possible phylogenetic relationships. It is recognized that no unequivocal hypothesized phylogenetic scheme of vascular plants exists. However, for expediency the classification of Tryon and Tryon (1982) was chosen for the ferns and allies, that of Foster and Gifford (1974) and Scagel et al. (1965) for the gymnosperms, and the system of Cronquist (1981) for the angiosperms. The overall totals for families, genera and species required to calculate the percentage of vascular epiphytes per taxon were taken from the same sources. In the case of the ferns, estimates for New World taxa were taken from Tryon and Tryon (1982), and for Old World taxa from Willis (1966) and Copeland (1947). Although these treatments of the ferns are quite different in their concepts of families, genera and species, they provide reliable, if not readily comparable, figures for numbers of taxa. For the angiosperms the number of genera and species for each family was compiled from Cronquist (1981), Willis (1966) or preferentially a family specialist when available (see Acknowledgments). In the cases where a range of numbers for total genera or species was given, the median of that range was used. The estimates for the Orchidaceae were taken from Atwood (1986) and readers are referred to that publication for his methods.

RESULTS

Epiphytic taxa are reported for all but two major divisions of extant vascular plants (TABLE 1). No epiphytes have been reported in the Ginkgophyta or the Coniferophyta. Ten percent of all vascular plant species (23,456 species) are epiphytic. Seven percent of the genera (876 genera), 19 percent of the families (84 families), 45 percent of the orders (44 orders), and 75 percent of the classes (6 classes) contain epiphytes (TABLE 2). The angiosperms account for the great majority of epiphytic taxa at all hierarchical levels. Eighty-nine percent of all epiphytic genera (782 genera) and species (20,859 species) of vascular plants are angiosperms. However, within the ferns and allies a higher percentage of the total (34 percent of families, 39 percent of genera, 29 percent of species) are epiphytes than in the gymnosperms or angiosperms. The gymnosperms are depauperate in epiphytes: only one-half percent of the species are epiphytes. Within the angio-

sperms only nine percent of the species are epiphytes, but 45 percent of the orders and 18 percent of the families contain epiphytes. The monocotyledons account for the majority of epiphytic genera (67 percent; 520 genera) and species (80 percent; 16,608 species) in the angiosperms. Within that class 31 percent of the species and 21 percent of the genera are epiphytic.

Twenty-three families of vascular plants contain over 50 epiphytic species each (TABLE 3). Sixteen of these families are angiosperms; the remaining seven are ferns and allies. These 23 families account for 98 percent of the epiphytic species and 87 percent of the epiphytic genera found in the vascular plants. The Orchidaceae is by far the largest family of epiphytes, containing 50 percent (440 genera) of all epiphytic genera and 60 percent (13,951 species) of all epiphytic species.

Forty-three genera of vascular plants have over 100 epiphytic species each (TABLE 4). Eight of these genera are ferns and 23 are orchids. These 43 genera comprise only five percent of all epiphytic genera, but contain 58 percent (13,544 species) of all epiphytic species.

Of the vascular plant families that include epiphytes, 45 percent (38 families) contain fewer than five epiphytic species, and 18 percent (15 families) contain only one epiphyte. Of the total number of epiphytic genera, 452 (52 percent) contain less than five epiphytic species, and 217 (25 percent) contain only a single epiphyte.

DISCUSSION

Madison (1977) reported 65 families, 850 genera and 28,200 species of vascular epiphytes. In the present compilation the number of families has increased by 19 and the number of genera by 26. The total number of species has decreased by 4,744. The decrease in the number of species is primarily due to the discrepancy in the number of epiphytic species reported in the Orchidaceae. Madison's figure of approximately 20,000 epiphytic orchid species is more than 6,000 species greater than the number reported here. If this difference is subtracted from Madison's 28,200 total epiphytic species, the remaining number is 1,300 less than the total number of epiphytic species reported here. Hence by correcting just for his estimate of epiphytic orchid species, the actual total number of epiphytic species known today is significantly greater than previously recorded. This reasoning also applies to Madison's overestimate of the number of epiphytic orchid genera. Estimates of the number of epiphytic taxa of ferns and gymnosperms has not significantly changed. Non-orchid genera and species of monocotyledons has increased over Madison's

TABLE 1. The systematic distribution of vascular epiphytes. For genera and species the number of epiphytic taxa is followed by the total number of taxa.

figures by 27 percent (17 genera) and 44 percent (807 species), respectively. Within the dicotyledons the number of epiphyte-containing families has increased by 37 percent (14 families), the number of genera by 32 percent (64 genera), and the number of species by 12 percent (451 species). Of the 65 families originally reported by Madison to contain epiphytes, estimates for all but 8 families (Aquifoliaceae, Gnetaceae, Myrtaceae,

Piperaceae, Pittosporaceae, Schizaeaceae, Vitaceae, and Zamiaceae) have been revised in some fashion (including name changes) in the current list.

Despite the differences in the number of epiphytic species estimated by Madison and in this report, the percentage of all species of vascular plants that are epiphytic is the same: ten percent. This similarity is accounted for by the fact that

TABLE 2. Synopsis of the distribution of vascular epiphytes in hierarchical taxonomic categories.

- Solanaceae	12	85	14	56	2,800	2

both Madison's total number of epiphytic species (due to an overestimate of the orchids) and his total number of vascular plants are proportionally higher than those reported here. The 231,638 total species of vascular plants used here to calculate the percentage of vascular epiphytes was derived from estimates provided by the references cited above. It is recognized that this is undoubtedly a low figure, especially in light of the many unnamed tropical species. Yet it is a verifiable figure that is sufficient for making the comparisons required here.

If all 23,456 epiphytic species occurred in the same family (obviously quite unlikely!), the origin of the epiphytic habit could be attributed to a single evolutionary event implying that colonization of the arboreal habitat was uncommon in the history of vascular plants. However, the distribution of these 23,456 species in 84 families, 44 orders, six classes and four divisions (TABLE 2) suggests that this character state has evolved independently many times. Even within families, many of the epiphytic genera apparently do not share recent common ancestors and most likely evolved the epiphytic habit independently. In the angiosperms, epiphytes are found in ten of the 11 subclasses and in 37 of the 83 orders (TABLE 2). In the dicotyledons, even though only three percent of the species are epiphytic, 44 percent of the orders contain epiphytes. Hence, rep-

resentation of epiphytism at the ordinal level provides a different perspective of the overall distribution within the class than does representation at the species level.

Only one family, the Vittariaceae, is exclusively epiphytic, and of the 23 largest epiphytic families (TABLE 3), only nine have a majority of species that are epiphytic. However, of the 43 largest epiphytic genera (TABLE 4), 39 are primarily epiphytic, and 23 are exclusively so. Exclusively epiphytic genera with fewer than 100 species are even more common, especially within the Cactaceae, Gesneriaceae, Melastomataceae, Orchidaceae, Pteridophyta, and Solanaceae.

Although epiphytic species are scattered throughout the vascular plants, the majority is concentrated in a relatively small number of families and genera. The 23 families that contain over 50 epiphytic species each (TABLE 3) makes up only 27 percent of all epiphytic families, but accounts for 87 percent of all epiphytic genera and 98 percent of all epiphytic species. The remaining two percent of epiphytic species are distributed among the remaining 73 percent of epiphytic families. Of those families 62 percent contain less than five epiphytic species and 25 percent contain only one epiphyte. The 43 largest genera (those containing 100 species or more; TABLE 4) comprise only five percent of all epiphytic genera, but account for 58 percent of all

epiphytic species. Thus 95 percent of the total number of epiphytic genera contain less than half of all the epiphytic species. Of those genera 55 percent have fewer than five epiphytic species while 26 percent contain only one.

The Orchidaceae, probably the largest family of flowering plants, contains over ten times more species of epiphytes and over eight times more genera of epiphytes than any other family of vascular plants (TABLE 3). Orchids constitute the majority of both epiphytic genera and species (TABLE 3) and account for 23 of the 43 largest

epiphytic genera (TABLE 4). The reason for the phenomenal speciation in orchids and especially the explosive radiation of the epiphytic habit has been debated elsewhere (e.g., Benzing, 1981; Dressler, 1981; Benzing & Atwood, 1984; Gentry & Dodson, 1986) and will not be discussed here.

In summary, epiphytes constitute an important component of the vascular plants, especially within the ferns and angiosperms, not only in terms of numbers of taxa, but with regards to biological diversity as well. As our knowledge of the taxonomy of tropical plants increases, new

accounts of epiphytes will undoubtedly be added to the list provided here. Further investigation of the ecology, reproductive biology, physiology and morphology of epiphytes is needed. Studies in these areas are still in their initial phases in comparison to those of their terrestrially-rooted relatives.

ACKNOWLEDGMENTS

I would like to thank J. Atwood, K. Barringer, D. Barrington, J. Beckner, H. Bedell, P. Berry, L. Besse, E. Christenson, T. Croat, A. Gentry, B. Hammel, M. Kimnach, J. Luteyn, H. Luther, T. Plowman, S. Renner, R. Scott, P. Stevens, R. Stolze, C. Taylor, and M. Turner for their advice. This update would not have been possible without their taxonomic expertise. Cheryl Roesel's help in preparation of the manuscript is much appreciated.

This paper is dedicated to Dr. Michael Madison.
