Abstract: We present a list of 151 species belonging to 109 genera, 18 subfamilies, and six families of butterflies collected at a subtropical dry forest in Guatemala from 2011 to 2012, with *Michaelus hecate* (Godman & Salvin, 1887) (Lycaenidae) and *Codatractus alcaeus alcaeus* (Hewitson, 1867) (Hesperiidae) as new records for the country.

Resumen: Se presenta una lista de 151 especies de 109 géneros, 18 subfamilias y seis familias de mariposas diurnas colectadas en un bosque seco subtropical en Guatemala de 2011 a 2012, con *Michaelus hecate* (Godman & Salvin, 1887) (Lycaenidae) y *Codatractus alcaeus alcaeus* (Hewitson, 1867) (Hesperiidae) como nuevos registros para el país.

Key Words: Central America, inventory, Neotropical, phenology, seasonal

INTRODUCTION

The Neotropics hosts the greatest diversity of butterflies of any major world biogeographic region (e.g., Heppner, 2004), and the fauna of Central America has been the subject of research for centuries (e.g., Godman & Salvin, 1879–1901). Biodiversity research on butterflies has been conducted throughout Central America, although a significant difference in surveying effort exists between the countries (e.g., Steinhäuser, 1975; DeVries, 1983, 1987, 1997; Maza *et al.*, 1989, 1991; Meerman, 1999; Shuey *et al.*, 2005; Maes, 2006, 2007; Chacón, 2009; Miller *et al.*, 2012; Llorente-Bousquets *et al.*, 2014). In Guatemala, there have been relatively few studies of the butterfly fauna (Bates, 1864–1865, 1866; Boisduval, 1870; Austin *et al.*, 1998; Barrios *et al.*, 2006; Salinas-Gutiérrez *et al.*, 2009, 2012; Salinas-Gutiérrez, 2013); no comprehensive inventory of a single region has been made since Austin *et al.* (1996) listed 535 species of Papilioidea (including Hesperiidae; van Nieukerken *et al.*, 2011) from northern Guatemala. Additional field surveys are clearly needed in Guatemala to bridge a gap in our understanding of the lepidopteran fauna of the Neotropics.

Here we present a list of papilionoid species collected at a subtropical dry forest in central Guatemala, with information on phenology and seasonal patterns. At this site, we recently discovered a hairstreak species, *Atlides gaumeri* (Godman 1901) (Lycaenidae: Theclinae), which represented a new record for Guatemala (Yoshimoto & Salinas-Gutiérrez, 2015). This report, together with the fact that the Guatemalan dry forests have had few biological studies despite their unique ecosystem

(CONAP-ZOOTROPIC-CECON-TNC, 2011; Ariano-Sánchez & Salazar, 2015), highlights the importance of conducting biodiversity research in those forests.

MATERIALS AND METHODS

This study was conducted in a woodland of Los Cerritos Municipal Park in the Baja Verapaz Department in central Guatemala (90°18'W, 15°05'N, 960–1160 m, 69 ha), including a neighboring small garden in the foothills. Average annual temperature and precipitation for the last five years (2006–2010) at San Jerónimo, ca. 7 km away from the study site, are around 21 °C and 1160 mm, respectively (Ministerio de Comunicaciones Infraestructura y Vivienda -INSIVUMEH-, 2013). The period of the rainy season is from late May or early June to October (Fig. 1), which is shorter than in the Petén

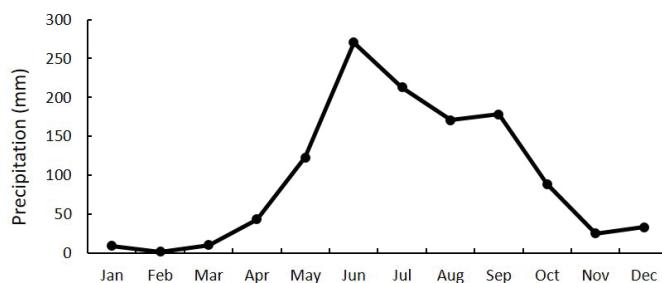

Fig. 1: Mean monthly rainfall at San Jerónimo, Baja Verapaz, Guatemala in 2006–2011, based on the data of Ministerio de Comunicaciones Infraestructura y Vivienda -INSIVUMEH- (2013).

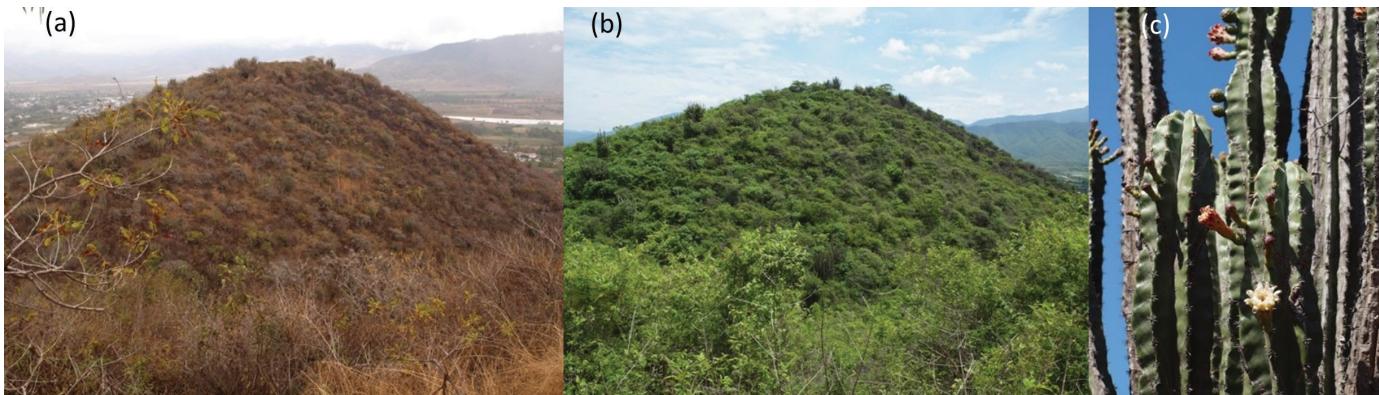

Fig. 2: Forest landscape of Los Cerritos Municipal Park in the (a) dry and (b) rainy seasons, and (c) a columnar cactus *Stenocereus pruinosus* (Cactaceae).

Department in northern Guatemala (May–January: Austin *et al.*, 1996). The landscape of Los Cerritos changes distinctively with the seasons; the whole forest turns green due to the simultaneous sprouting of leaves in the beginning of the rainy season (Fig. 2a, b). The vegetation is subtropical dry forest or subtropical thorn forest (Holdridge, 1967; Cruz, 1982), with various aculeate plants; there are more than ten species of Cactaceae at Los Cerritos, the most dominant of which is a columnar cactus *Stenocereus pruinosus* (Otto) Buxb. (Fig. 2c).

We conducted field surveys from January 2011 to November 2012 (for 76 days in 2011 and 33 days in 2012), collecting adult butterflies with an insect net along trails, on the hill summit, and in the garden. We used banana-baited traps only a few days to sample fruit-feeding butterflies. The surveys were mostly done from 09:00–13:00, because in the rainy season it often rains in the late afternoon when many adult butterflies are much less active. The individuals collected were mounted and identified at the species or subspecies level according to Warren *et al.* (2017). All the voucher specimens were deposited at the Laboratorio de Entomología Sistemática, Universidad del Valle de Guatemala in Guatemala City and at the FUNDEMABV office in Salamá, Baja Verapaz, Guatemala.

RESULTS

In total, 332 individuals of 151 species (80 subspecies) in 109 genera from 18 subfamilies were collected (Appendix). Theclinae sp.1, based on a partly damaged specimen, was excluded from our species count, since it could not be positively identified. Among the six families recorded, Nymphalidae was the richest (56 species), followed by Hesperiidae, Lycaenidae, Pieridae, Riodinidae, and Papilionidae (41, 24, 14, 10, and 6 species, respectively).

One hairstreak species (Lycaenidae: Theclinae) and one skipper species (Hesperiidae: Eudaminae) had not previously been recorded from Guatemala, constituting new records for the country:

***Michaelus hecate* (Godman & Salvin, 1887).** GUATEMALA, Baja Verapaz, Salamá, Los Cerritos ($N15^{\circ}05'$, $W90^{\circ}18'$, altitude: 960–1160 m). One specimen: 29 September 2011, M0182. Collected by Jiichiro Yoshimoto. Identified by José Luis Salinas-Gutiérrez. The specimen was deposited in the Colección de Artrópodos, Laboratorio de Entomología

Sistemática, Universidad del Valle de Guatemala, and is being catalogued (Fig. 3a). Distribution: Eastern and western Mexico to Costa Rica (Warren *et al.*, 2017).

***Codatractus alcaeus* alcaeus (Hewitson, 1867).** GUATEMALA, Baja Verapaz, Salamá, Los Cerritos ($N15^{\circ}05'$, $W90^{\circ}18'$, altitude: 960–1160 m). Two specimens: 28 March 2011, M0229; 3 May 2011, M0230. Collected by Jiichiro Yoshimoto. Identified by Mercedes Barrios. The specimens were deposited as above, and are being catalogued (Fig. 3b). Distribution: Southern Texas to Costa Rica (Warren *et al.*, 2017).

Thirty-nine species occurred in both dry (November–April) and rainy seasons (May–October); among them, *Phoebis sennae marcellina* (Cramer, 1777) (Pieridae: Fig. 4b), *Calephelis* sp.1 (Riodinidae), and *Chlosyne lacinia lacinia* (Geyer, 1837) (Nymphalidae: Fig. 4g) were collected in five or six months (Appendix), indicating that they have multiple broods throughout the year. By contrast, 17 out of 20 identified species of hairstreaks (Lycaenidae: Theclinae) were observed only in the middle of the rainy season (June–September; Appendix).

DISCUSSION

Our preliminary surveys yielded more than 150 butterfly species at Los Cerritos, demonstrating that this somewhat isolated forest hosts a relatively high lepidopteran diversity for its small area (ca. 70 ha). This is the first butterfly inventory for Guatemalan dry forests, adding to our knowledge of the Neotropical lepidopteran fauna and serving as an important baseline for future entomological research in the Guatemalan dry forests. Furthermore, the results of such studies will provide useful information for implementing conservation plans in those forests. Our species list, however, is still incomplete due to the limited sampling effort, and Los Cerritos will surely harbor many more species than those we sampled. This emphasizes the necessity of more surveys to elaborate a more comprehensive butterfly checklist of Guatemalan dry forests.

Our finding of *Codatractus alcaeus* and *Michaelus hecate* represents the first record for Guatemala of these species. Austin *et al.* (1998) listed *C. alcaeus* as a species with potential occurrence in the country, based on reports that it was sampled from the adjacent countries (Mexico, El Salvador,

Fig. 3: Butterfly species that are newly recorded for Guatemala; (a) *Michaelus hecate* (Godman & Salvin, 1887) (Lycaenidae: Theclinae) and (b) *Codatractus alcaeus alcaeus* (Hewitson, 1867) (Hesperiidae: Eudaminae). Dorsal and ventral views are respectively shown at the left and right in each photograph.

and Honduras). *Michaelus hecate* was collected from Chiapas (Luis-Martínez *et al.*, 2011), El Salvador (Warren *et al.*, 2017), and Nicaragua (Robbins *et al.*, 2012), which also implied its probable distribution in Guatemala. Our results have confirmed these predictions and thus filled a gap in our knowledge of the geographic distribution of these species.

Ninety-three species collected at Los Cerritos were also sampled at Tikal (Austin *et al.*, 1996). It is notable that more than 60% of the species recorded at our study site are also found at Tikal, a distant site (ca. 240 km away) with very different environmental conditions, although at present we cannot make quantitative comparisons of species composition between these sites, because, as previously mentioned, our sampling effort was much smaller than Austin *et al.* (1996), with the latter study involving a 3-year intensive survey in an extensive area (576 km²).

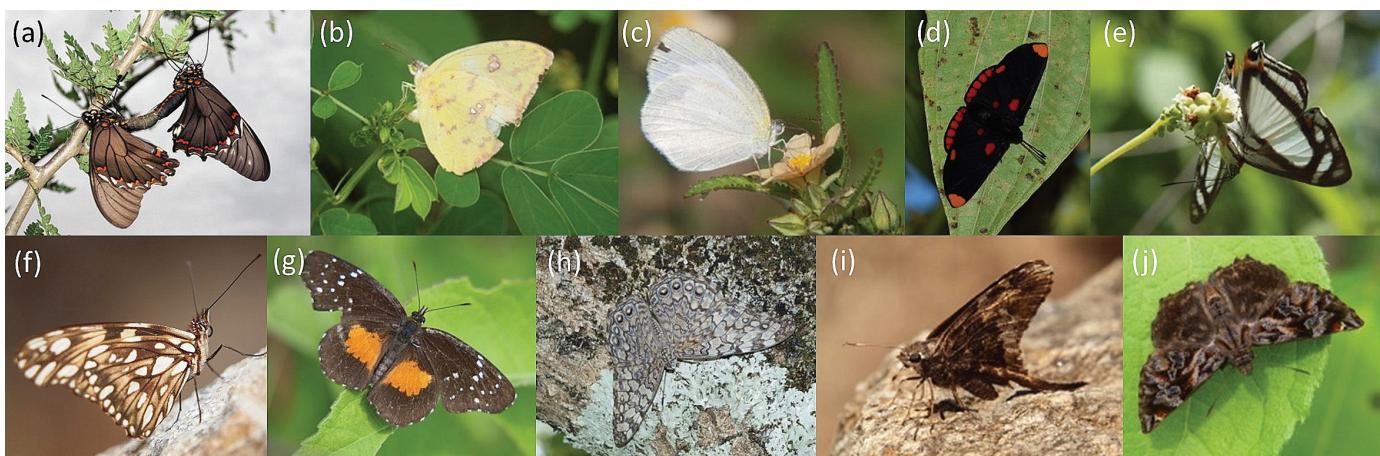

Fig. 4: Butterfly species that were commonly observed at Los Cerritos Municipal Park: (a) a copulating pair of *Battus polydamas* (Papilionidae), (b) an ovipositing female of *Phoebeis sennae*, (c) *Eurema daira* (both Pieridae), (d) *Melanis pixe*, (e) *Thisbe lycorias* (both Riodinidae), (f) *Dione juno*, (g) *Chlosyne lacinia*, (h) *Hamadryas februa* (all Nymphalidae), (i) *Typhedanus undulatus*, (j) *Noctuana stator* (both Hesperiidae).

An apparent seasonal pattern was seen in Theclinae, where almost all the species occurred uniquely in the rainy season, which would be an interesting phenomenon to investigate further. Although we cannot discuss the seasonality in detail because the sampling effort differed across months, it should be noted that more species were observed in the wettest months (June–September; Fig. 1) than in the other months in both years (79 and 76 species, respectively, in 2011, and 50 and 25 species, respectively, in 2012), despite the former period having fewer observation dates than the latter (33 and 43 days, respectively, in 2011, and 16 and 17 days, respectively, in 2012). Quantitative monthly monitoring of butterflies, ideally in relation to abiotic and biotic factors, is necessary to examine such seasonal patterns, which in turn may elucidate the phenology of each species.

ACKNOWLEDGMENTS

We thank Andrew Warren, John Shuey, and an anonymous reviewer for their critical reading of the manuscript and for providing us valuable comments and suggestions. We also thank Robert K. Robbins, Arturo Arellano Covarrubias, and Ichiro Nakamura for identifying some of the specimens, and the members of Fundación de Defensa del Medio Ambiente de Baja Verapaz (FUNDEMABV) for their logistic assistance. This work was part of the Japan Overseas Cooperation Volunteer (JOCV) program organized by Japan International Cooperation Agency (JICA).

APPENDIX: Butterfly species collected at Los Cerritos Municipal Park, Guatemala in 2011–2012. The numbers of individuals sampled and the months when they were collected are also given; the number of individuals does not represent relative abundance because exhaustive collecting of all observed individuals was not done. The species that were newly recorded for Guatemala are shown in bold. Identifications were made using Warren *et al.* (2017).

^A Species shared with those collected by Austin *et al.* (1996).

*Excluded from the count of the number of species.

**This is a species complex, which includes several species in Costa Rica (Hebert *et al.*, 2004; Brower, 2006, 2010). We were not able to identify our samples to species due to lack of DNA barcoding analyses. The two individuals collected might also represent two different species.
